Lecture 15
Dealing with Failure
Announcements

• Today’s Topics
  – Dealing with Failure
  – Failure and Failure Causes
  – Failure Identification
  – Failure Detection
  – Failure Recovery
Motivation

• The world is imperfect
  – Sensors give wrong readings
  – Motors turn too fast, too slow, too much, or too little
  – Wheels don’t grip the surface properly
  – Lighting conditions change

• This is normal
  – Humans deal with these kinds of problems all the time
  – We learn how to deal with failure

• How do we get robots to deal with them as well?
Dealing with Failure

• Need to do two things
  – Identify when a failure has occurred
  – Respond to the failure

• Example: Missing your exit on the highway
  – Identify that you have gone too far
  – Turn around and back track
Failure and Failure Cause

• **Def:** *Failure* is a state that is not anticipated by the design

• **Def:** *Failure cause* is the physical or functional reason for the failure
  – I.e., Why did failure occur?
  – Also known as *failure mode*

• Examples:
  – The furnace stopped working because *it ran out of oil*
  – We missed the exit because *we did not see the sign*
  – The robot missed the line because *it drove over it too quickly*

• **Key Observation:**
  – We can only deal with failures that we can foresee
  – I.e., What can go wrong?
Failure Manifestation

- **Def:** *Failure manifestation* is the detectable effect of the failure

- **Examples:**
  - *The house is cold* because the furnace is not working
  - *We have driven too long* because we missed the exit
  - *Our arm hurts* because we have broken it

- **Key Idea:** To identify failure, it must manifest itself in a detectable way
Failure Identification

• **Idea:** We can identify that a failure has occurred from its manifestation

• E.g., We identify that
  – The furnace must not be working because the house is cold
  – We must have missed the exit because we have driven too long
  – Our arm must be broken because it really hurts

• **Idea:** To identify a failure, we need to
  – Determine what can cause the failure
  – How the failure manifests
Enumerating Failures

• When designing a program we need to (attempt to) enumerate all relevant failures:
  – Assume things will go wrong
  – Ask “What can go wrong?”
  – Ask “How is failure manifested?”

• Narrow the enumeration to:
  – Failures we can deal with
  – Failure causes we understand
  – Failure manifestations we can identify

• Systems fail because designers fail to identify all relevant failure causes
Examples of Failures and Causes

• Ground proximity sensor fails to register dark / light
  – Sensor’s distance to ground changed
• Horizontal proximity sensor fails to register object
  – Object has an odd shape
  – Object has an odd surface
• Horizontal proximity sensor registers ghost objects
  – Other robots nearby emitting infra-red light
• Robot does not make sufficiently precise movement
  – Tires are not properly aligned
  – Motors are rotating too fast
  – Wheels don’t grip the surface properly

• In all cases the sensor or actuator may be broken
• How do we detect failures?
Mechanisms for Detecting Failure

• Unexpected external events
  – Sensors register an unexpected changes in environment
    • Sensors give false readings
    • Sensors give true readings of unexpected conditions
  – Actuators report status errors
    • Actuator fails to perform specified task
    • Actuator reports error where none has occurred

• Lack of expected external events
  – A timer expired while waiting for an expected event
    • Sensor fails to register the expected event
    • Expected event does not occur
  – Actuators fail to move the prescribed amount
    • Encounter unexpected resistance

• Unexpected (or lack there of) internal events
  – Programs run code they are not supposed to (bugs)

→ Unexpected: A difference between the anticipated and measured
Failure Response

- Once we determine that a failure has occurred, we need to respond to it
- **Def:** *Response mechanisms* are parts of the program that respond to the failure
- One approach is to put system in safe state and shut down
  - E.g., nuclear reactors
- This is not always possible if
  - System is inaccessible
    - E.g., rovers on Mars
  - System is mission critical
    - E.g., airplane
- In these cases the system must *recover* from the failures
Failure Recovery

- Recall: A failure occurs when a system enters an unexpected state
- **Def:** A *recovery mechanism* returns the system to a normal state

- Recovery mechanisms are specific to each failure
- Examples:
  - If an exit is missed, *backtrack to the exit*
  - If the furnace is broken, *call landlord*
  - If your arm is broken, *see a doctor*
- For our purposes: *return the robot to its last "normal" state*
  - Find the line if it is lost
    - Recheck sensors
    - Retry actuator operation
- If the recovery mechanism fails, we need a recovery mechanism for the recovery mechanism...
Modeling Failure Identification and Recovery

• We need to model or represent how we
  – Identify failure
  – Respond to failure
  – Recover from failure

• What should we use?
State Transition Diagrams

• Idea: Use state transition diagrams to represent possible failures and recovery mechanisms
• Example: Crossing the Street
A Missed Line in Follow the Line

- **Right state**
  - Sensor reports light
  - On left side of line
  - Moving to the right
  - Timer running

- **Left state**
  - Sensor reports dark
  - On the line
  - Moving to the left

- **Lost state**
  - Timer expired
  - Sensor reports light
  - On right side of the line
  - Moving to the left

- **Found state**
  - Sensor reports dark
  - On the line
  - Moving left
Observations

• Error identification and response can add much more complexity to your program
  – 80% of a typical application deals with error handling

• The error response itself may fail

• State transition diagrams are an easy way to reason about errors
